What are the differences between FASD and neonatal abstinence syndrome (NAS)?

Using substances like alcohol or opioids during pregnancy can affect the fetus. Drinking during pregnancy can cause fetal alcohol spectrum disorders (FASD). Using certain substances like opioids (such as heroin, codeine, oxycodone, methadone, and/or buprenorphine), some prescription medications (like antidepressants) and illegal substances (such as meth) have been found to cause NAS as well.

Although both FASD and NAS are caused by substance use during pregnancy, there are many differences between these two conditions. One of the major differences is that NAS can be treated, but FASD is lifelong.

Below we have listed some of the common symptoms of FASD and NAS. Things that are in bold are effects that are seen in both conditions. Please note that not every person with prenatal substance exposure will have an FASD or NAS. Not every person with FASD or NAS will have all of the effects listed.
